

Abstract of the Disclosure:

A safety needle cap for a syringe completely covers the hypodermic needle during non-use or between injections. The needle can be easily exposed with a reduced danger of  
5 accidental needle-stick injury. The needle cap can be unlocked from the closed position by being rotated, and then slid backwards onto the syringe barrel by a defined travel distance. Several settings, up to the full extension of the needle, are possible. After use, the needle retracted into the  
10 cap, once more preventing needle-stick injury.
